

What is adjustable capacitance?

Adjustable capacitance makes these capacitors essential for fine-tuning electronic circuits. In electronic applications like radios and oscillators, their ability to adjust capacitance by changing surface area, plate spacing, or dielectric material allows for precise control.

How does a LM317 voltage regulator IC work?

This voltage regulator circuit is very simple. The capacitor C1 used for the filtering of DC input voltage and further fed to the Vin pin of the LM317 voltage regulator IC. The adjustable pin is connected with the two external resistor, and connected with the Vout pin of the IC.

How do electronic components adjust capacitance?

In electronic applications like radios and oscillators, their ability to adjust capacitance by changing surface area, plate spacing, or dielectric material allows for precise control. Anyone interested in electronics must understand these components' operation and maintenance, whether they are electronically or mechanically adjusted.

What is a variable capacitor?

Learn about variable capacitors, essential parts of many electronic devices. Adjustable capacitance makes these capacitors essential for fine-tuning electronic circuits.

How to adjust LM317 output voltage?

Firstly, you have to decide what output you want. As the LM317 having an output voltage range of 1.25V to 37V DC. We can adjust the output voltage by two external resistor connected through the adjustable pin of the IC. If we talk about the input voltage it can be in range of 3 to 40V DC.

What are adjustable voltage regulators?

Here we would like to talk about adjustable voltage regulators. They require more complicated circuits than linear. They can be used to produce different fixed voltage outputs depending on the circuit and also adjustable voltage via potentiometer.

Pin#03: Ground. The ground pin is connected to the ground of the circuit. Pin#04: Feedback. The feedback is an input pin used to set output voltage in case of adjustable output. To adjust the output voltage, it is connected to the midpoint ...

A 0.1mF bypass capacitor on the ADJ pin is required if the load current varies by more than 1A/msec. Improved ripple rejection (80dB) can be accomplished by adding a 10mF capacitor from the ADJ pin to ground.

- Trigger Pin (Pin2) gets grounded - Since this applied voltage at Pin2 (0V) is less than 1/3rd of the supply voltage (5V), the output at Pin3 turns ON - And at the same time, the Discharge Pin (Pin7) disconnects internally from 0V - This causes the capacitor to charge via the resistor or potentiometer - Now, the voltage across Pin6 starts increasing - As soon as the ...
