

Analysis of light voltage of silicon photovoltaic cells

Are crystalline silicon solar cells efficient under varying temperatures?

However, the efficiency of these cells is greatly influenced by their configuration and temperature. This research aims to explore the current-voltage (I-V) characteristics of individual, series, and parallel configurations in crystalline silicon solar cells under varying temperatures.

How is a photovoltaic module prepared?

A photovoltaic module has been prepared from silicon solar cells fabricated by Suzhou Talesun Solar Technologies Co., Ltd. Short-circuit current and open-circuit voltage of the module has been studied as a function of the illumination intensity and temperature in laboratory conditions.

How is voltage measured in a solar cell?

Open Circuit Voltage (V_{oc}): The V_{oc} was measured by determining the potential across the solar cell when there was no current flowing (at maximum resistance position). Short Circuit Current (I_{sc}): The I_{sc} was measured by setting minimum resistance, resulting in maximum current flow.

What is the experimental setup for crystalline silicon solar cells?

The experimental setup, as shown in Figure 2, is capable of generating controlled conditions for measuring the IV (current-voltage) characteristics of crystalline silicon solar cells in different configurations (individual, series, and parallel). The key components of the experimental setup included: Figure 2. Experimental setup.

How effective is a silicon solar module?

It features an outstanding cell effectiveness about 26.7 % and a maximum module effectiveness of 24.4 %. The existing commercial silicon solar modules, such as monocrystalline (m-Si) and polycrystalline silicon (p-Si), are extensively utilized and make up over 90 % of total PV output.

Is crystalline silicon a good choice for solar power?

The crystalline silicon has established a significant lead in the solar power sector, holding a market share of roughly 95 %. It features an outstanding cell effectiveness about 26.7 % and a maximum module effectiveness of 24.4 %.

The IV curve of a solar cell is the superposition of the IV curve of the solar cell diode in the dark with the light-generated current.¹ The light has the effect of shifting the IV curve down into the fourth quadrant where power can be extracted from the diode. Illuminating a cell adds to the normal "dark" currents in the diode so that the diode law becomes:

The solar cell design metal/SiNx/n + Si/p-Si/metal has been considered. The dielectric permittivity of all layers is 11.9. The effective density of states of conducting bands and valence bands for all layers are 2.8×10^{19} cm⁻³ and 1.04×10^{19} cm⁻³, respectively. The rest parameters of the solar cell design are summarized in Table 1.
