Abnormal Charge Current Detection . the VM pin voltage drops below the charger detection voltage (V_{CHA}) during charging under the normal condition and it continues for the overcharge detection delay time (t_{CU}) or longer, the +0 turns the charging control FET off and stops charging. This action is called abnormal charge current detection.

The MAX17335 is a 35mA I_Q stand-alone charger, fuel gauge, protector, and battery internal self-discharge detection IC for 1-cell lithium-ion/polymer batteries. When a voltage source is present, the IC regulates charging by modulating the charge N-FET, using AccuCharge(TM)charger ...

Your device can distinguish a charger from a host by measuring the voltage on CC1 and CC2. It should (and probably will) draw 1.5A only if it detects a charger. The voltage is determined by certain pull-up (charger, host) and pull-down (device) resistor values on CC1 and CC2. You should have no problem connecting your device to the charger.
