

What is a battery electrode manufacturing procedure?

The electrode manufacturing procedure is as follows: battery constituents, which include (but are not necessarily limited to) the active material, conductive additive, and binder, are homogenized in a solvent. These components contribute to the capacity and energy, electronic conductivity, and mechanical integrity of the electrode.

What is the electrode structuring method?

This was developed on a on a pilot-scale roll-to-roll tool using a variety of different active battery materials (LFP,NMC,LTO). This electrode structuring method creates a bi-continuous electrolyte and electrode network with excellent ion and electron transport reducing the charge-transport challenges in thick electrodes.

How can electrode architecture be manipulated?

Manipulation of electrode architecture on both the macro- and micro-scale was achieved by Li et al. by combining an additive manufacturing extrusion process with exposure to an electric field. In the additive manufacturing procedure, a base coating was applied to the current collector, followed by a digitally structured layer.

What are the advantages of increasing the thickness of battery electrodes?

Increasing the thickness of battery electrodes is an attractive approach to reduce the fraction of battery parts that do not store energy, such as current collectors and separators. As depicted in the image below, increasing the thickness of battery electrodes from 50 μm to 500 μm allows to reduce the weight and cost of batteries.

What are the challenges of thicker battery electrodes?

However, the fabrication of thick electrodes holds challenges of its own such as cracking or flaking during the electrode production and limitations in ion and electron transport. Our research group has developed a number of techniques to create thicker battery electrodes.

What techniques are used to elucidate electrode microstructure?

Two techniques are used primarily to elucidate electrode microstructure: focused ion beam-scanning electron microscopy (FIB-SEM) and X-ray computed tomography (XCT).

Two of the main factors influencing the performance of Li-ion battery (LIB) electrodes are the kinetic losses due to the charge transfer resistance of the active material and the ionic transport resistance in the electrolyte

phase within the electrode pores (). Seeking to increase the energy density of LIBs, ever higher active material loadings are applied, resulting ...

The noncontacted exposed ends of the electrode and tape were placed in opposing clamps. 39 Because the clamps are colinear, the tensile peel force is applied parallel to the sample surface, albeit with a relatively rigid foil tape that tends to create a 90° bend in both foil and sample near the moving line of contact (see Fig. 3).

Uneven EV battery electrode coating can expose electrically conductive materials, causing irreparable damage to the electrode sheet and potentially causing an electrical short or fire. In-line machine vision inspections allow ...

One-Step Pressing, it is rolling only once to achieve the designed thickness and density of the battery electrode. Two-Step Pressing, it is rolling the battery electrode to a certain thickness (such as 90mm) at first time, and achieve the designed thickness (such as 70mm) and desired density through the second time pressing.

This paper presents a novel method for lithium-ion battery electrode (LIBE) surface quality assurance. First, based on machine vision, an automatic optical inspection system is developed to check defects on LIBE. In addition, a background normalization algorithm is put forward to preprocess the large-scale LIBE with inhomogeneous thickness in uneven ...
