## **SOLAR** PRO. Capacitor influence on frequency

## How does frequency affect a capacitor?

As frequency increases, reactance decreases, allowing more AC to flow through the capacitor. At lower frequencies, reactance is larger, impeding current flow, so the capacitor charges and discharges slowly. At higher frequencies, reactance is smaller, so the capacitor charges and discharges rapidly.

What is the interaction between capacitance and frequency?

The interaction between capacitance and frequency is governed by capacitive reactance, represented as XC. Reactance is the opposition to AC flow. For a capacitor: where: Capacitive reactance XC is inversely proportional to frequency f. As frequency increases, reactance decreases, allowing more AC to flow through the capacitor.

What happens if you increase the capacitance of a capacitor?

At zero frequency (DC) the capacitor is an open circuit, i.e. infinite impedance. The more we increase the capacitance of a capacitor -> for the same charge at the plates of the capacitor we get less voltagewhich resists current from the AC source. First, let's look at how the capacitive reactance is obtained.

How does a capacitor affect an amplifier's response?

For large frequency the coupling and bypass capacitors behaves like ac shorts and has no effecton the amplifier's response. Inner transistor junction capacitance,though,do come into play,dropping an gain of amplifier and causes phase shift as signal frequency rises.

Why does capacitive reactance decrease with increased capacitance?

It is easy to prove why capacitive reactance decreases with increased capacitance. The more we increase the capacitance of a capacitor -> for the same charge at the plates of the capacitor we get less voltage which resists current from the AC source. But why is reactance decreased with the increase of the frequency of the applied signal?

What is the relationship between capacitive reactance and frequency?

Answer: As frequency increases, capacitive reactance decreases, reducing capacitor impedance, and allowing more AC to flow. In summary, capacitance and frequency have an inverse relationshipgoverned by capacitive reactance. Understanding this interplay is key to properly designing and analyzing AC circuits containing capacitors.

Here the emission spectrum is mainly determined by the value of the decoupling capacitor itself, which in this case remained unchanged. The additional parasitic inductance caused by the corner arrangement has no influence in this frequency range. However, as can be seen in the higher frequency range there is a significant difference.

In capacitively coupled amplifiers, the coupling and bypass capacitors affect the low frequency cutoff. These capacitors form a high-pass filter with circuit resistances. A typical BJT amplifier has three high-pass filters. For example, the input coupling capacitor forms a high-pass filter with the input resistance of the amplifier:
