## What is a capacitive voltage divider?

This capacitive reactance produces a voltage drop across each capacitor, therefore the series connected capacitors act as a capacitive voltage divider network. The result is that the voltage divider formula applied to resistors can also be used to find the individual voltages for two capacitors in series. Then:

#### Which capacitors are connected in series?

The two capacitors which are connected in series have the capacitance values of 10uF and 22uF respectively. Here the circuit voltage is 10V, this voltage is distributed between both capacitors. In the series connection all the capacitors have same charge (Q) on it but the supply voltage (V S) is not same for all capacitors.

## Does a capacitor divider work as a DC voltage divider?

We have seen here that a capacitor divider is a network of series connected capacitors, each having a AC voltage drop across it. As capacitive voltage dividers use the capacitive reactance value of a capacitor to determine the actual voltage drop, they can only be used on frequency driven supplies and as such do not work as DC voltage dividers.

What happens if series capacitor values are different?

However, when the series capacitor values are different, the larger value capacitor will charge itself to a lower voltage and the smaller value capacitor to a higher voltage, and in our second example above this was shown to be 3.84 and 8.16 volts respectively.

Why does a capacitive voltage divider always stay the same?

Because as we now know, the reactance of both capacitors changes with frequency (at the same rate), so the voltage division across a capacitive voltage divider circuit will always remain the same keeping a steady voltage divider.

How to calculate the cutoff frequency of a capacitive voltage divider?

The cutoff frequency (fc) of a capacitive voltage divider can be calculated using the following formula: fc = 1 /[2p (C1 +C2)R]By adjusting the capacitor values and load resistance,we can design a capacitive voltage divider that acts as a high-pass filter with the desired cutoff frequency.

For parallel capacitors, the analogous result is derived from Q = VC, the fact that the voltage drop across all capacitors connected in parallel (or any components in a parallel circuit) is the same, and the fact that the charge on the single equivalent capacitor will be the total charge of all of the individual capacitors in the parallel combination.
