# Summary analysis of negative electrode materials for chemical batteries

What are negative electrode materials for Na-ion batteries?

This paper sheds light on negative electrode materials for Na-ion batteries: carbonaceous materials,oxides/phosphates (as sodium insertion materials),sodium alloy/compounds and so on. These electrode materials have different reaction mechanisms for electrochemical sodiation/desodiation processes.

#### What are the limitations of a negative electrode?

The limitations in potential for the electroactive material of the negative electrode are less important than in the past thanks to the advent of 5 V electrode materials for the cathode in lithium-cell batteries. However, to maintain cell voltage, a deep study of new electrolyte-solvent combinations is required.

Can nibs be used as negative electrodes?

In the case of both LIBs and NIBs, there is still room for enhancing the energy density and rate performance of these batteries. So, the research of new materials is crucial. In order to achieve this in LIBs, high theoretical specific capacity materials, such as Si or P can be suitable candidates for negative electrodes.

Why are electrode materials important for long cycle life Na-ion batteries?

These electrode materials have different reaction mechanisms for electrochemical sodiation/desodiation processes. Moreover, not only sodiation-active materials but also binders, current collectors, electrolytes and electrode/electrolyte interphase and its stabilization are essential for long cycle life Na-ion batteries.

What is a high-energy negative electrode system?

The incorporation of a high-energy negative electrode system comprising Li metal and siliconis particularly crucial. A strategy utilizing previously developed high-energy anode materials is advantageous for fabricating solid-state batteries with high energy densities.

#### Which metals can be used as negative electrodes?

Lithiummanganese spinel oxide and the olivine LiFePO 4, are the most promising candidates up to now. These materials have interesting electrochemical reactions in the 3-4 V region which can be useful when combined with a negative electrode of potential sufficiently close to lithium.
