What are the capacitors for data acquisition

How do data acquisition systems work?

SOLAR PRO

These measurement signals are used as inputs to the data acquisition system (DAQ or DAS). Data acquisition systems are at the core of all devices that require the input of a measured physical or process variable. The acquired data is usually sent to a microprocessor for processing and analysis.

What is a precision data acquisition signal chain?

Typical precision data acquisition signal chain. Analog Devices signal chain µModule ® data acquisition solutions help solve some of the power design pain points, such as optimized layout of traces, the addition of decoupling capacitors, and in some cases, power management components such as LDO regulators.

How do power supplies affect data acquisition performance?

When optimizing data acquisition (DAQ) systems, designers must carefully consider the effects of power supplies on high precision performance. Often, the power supply circuitry includes a combination of low dropout linear regulators and dc-to-dc switch-mode converters. One drawback of switch-mode converters is that they produce an output ripple.

What is a data acquisition system (Daq or Das)?

The out-put signals from these transducers are usually continuous (i.e., analog) in magnitude and time. These measurement signals are used as inputs to the data acquisition system (DAQ or DAS). Data acquisition systems are at the core of all devices that require the input of a measured physical or process variable.

Which capacitor should be placed near a power supply pin?

For amplifiers,0.1 µF ceramic capacitors are placed as close to the power supply pins as possible to reduce high frequency coupling. In addition, to provide low frequency decoupling, large 10 mF tantalum capacitors are connected in parallel, and typically placed closer to the supply source.

What are industrial data acquisition systems?

The two most common applications for industrial data-acquisition systems are in process control and factory automation. Process-control systems typically detect or measure multiple physical quantities, such as temperature and pressure, within one system, while factory automation usually monitors one physical quantity across multiple sys-tems.
