SOLAR PRO. Working principle of thin film solar photovoltaic panels

How are thin-film solar cells produced?

Thin-film solar cells are produced through the deposition of one or more thin layers (referred to as thin films or TFs) of photovoltaic material onto a substrate.

What is a thin-film solar PV system?

This is the dominant technology currently used in most solar PV systems. Most thin-film solar cells are classified as second generation, made using thin layers of well-studied materials like amorphous silicon (a-Si), cadmium telluride (CdTe), copper indium gallium selenide (CIGS), or gallium arsenide (GaAs).

What is a thin film solar cell?

Light Weight: Thin-film solar cells are exceptionally lightweight due to their thin layers of photovoltaic material. Traditional silicon cells are typically 200-500 microns (µm) thick, whereas thin-film solar cells typically range from 1-15 µm - thinner than a human hair.

Why do thin-film solar cells produce less electricity per square foot?

The reason for the low efficiency of thin-film solar cells lies in the physical properties of their materials, which do not absorb sunlight as efficiently as the crystalline silicon used in other types of solar panels. Consequently, thin-film solar cells produce less electricity per square foot.

Are thin-film solar cells a good choice?

Thin-film solar cells typically have a lower efficiency of 7-22%, compared to traditional monocrystalline and polycrystalline types. The thin photovoltaic layers of thin-film cells limit their sunlight absorption and electricity generation capabilities, although this same characteristic grants them greater flexibility.

What are the different types of thin-film solar cells?

There are three main types of thin-film solar cells, depending on the type of semiconductor used: amorphous silicon (a-Si), cadmium telluride (CdTe) and copper indium gallium deselenide (CIGS). Amorphous silicon is basically a trimmed-down version of the traditional silicon-wafer cell.
